

## **It Remains “Appropriate and Necessary” to Regulate Toxic Air Emissions from Coal- and Oil-fired Electric Generating Units**

By Barbara Morin and Paul J. Miller

April 17, 2019

### **I. Introduction**

#### *a. Overview*

The Northeast States for Coordinated Air Use Management (NESCAUM)<sup>1</sup> has developed this report in response to the February 7, 2019 U.S. Environmental Protection Agency (EPA) Proposed Rule *National Emission Standards for Hazardous Air Pollutants: Coal- and Oil-Fired Electric Utility Steam Generating Units—Reconsideration of Supplemental Finding and Residual Risk and Technology Review*<sup>2</sup> (referred to here as the “Reconsideration Proposal”). In this action, EPA has proposed to withdraw its long-standing and well-documented “appropriate and necessary” finding first made in 2000<sup>3</sup> and subsequently reaffirmed in 2012<sup>4</sup> and 2016.<sup>5</sup> The finding underpins pollution control requirements for mercury and other hazardous air pollutants (HAPs, also referred to as “air toxics”) emitted by coal- and oil-fired electric generating units (EGUs). EPA established these requirements in the 2012 Utility Mercury and Air Toxics Standards (MATS)<sup>6</sup> and the affected EGUs have now complied with the emission limits. MATS continued existence, however, could be put at legal risk should EPA withdraw the rule’s “appropriate and necessary” basis.

Prior to MATS, the states in the NESCAUM region, as well as a number of other states, developed their own state programs to control mercury, an important air toxic emitted by coal-fired EGUs. The state rulemakings often took a “multi-pollutant” approach that also included requirements to reduce emissions of acid- and ozone-forming precursor pollutants (e.g., nitrogen oxides, sulfur dioxide). During the development of their rules, the states used a number of approaches in assessing the costs, benefits, and feasibility of controlling multiple pollutants

---

<sup>1</sup> NESCAUM is the regional association of the state air pollution control agencies in Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Rhode Island, and Vermont ([www.nescaum.org](http://www.nescaum.org)).

<sup>2</sup> 84 Fed. Reg. 2670-2704 (February 7, 2019).

<sup>3</sup> 65 Fed. Reg. 79,825-79,831 (December 20, 2000).

<sup>4</sup> 77 Fed. Reg. 9304-9513 (February 16, 2012).

<sup>5</sup> 81 Fed. Reg. 24,420-24,452 (April 25, 2016).

<sup>6</sup> 77 Fed. Reg. 9304-9513 (February 16, 2012).

within a single program. Because the state rules pre-dated the original federal promulgation of MATS, they served as early examples of the practicality of the later MATS requirements.

Mercury has received special attention because of its elevated presence in commercially and recreationally important fish consumed by the public, as well as its adverse environmental impacts on loons and other wildlife. Due to elevated fish mercury levels, all the NESCAUM states have issued fish consumption advisories for fish caught in most or all the waters within each state.<sup>7</sup> To address this problem, New York and the New England states successfully petitioned EPA in 2007 to establish a Northeast Regional Mercury Total Maximum Daily Load (TMDL) under section 303(d) of the Clean Water Act.<sup>8</sup> The Northeast Regional Mercury TMDL established a mercury budget at a reduced level that the states project will allow for safe fish consumption and the lifting of state fish consumption advisories.

In setting their regional TMDL, the Northeast states considered multiple cross-media mercury sources. These encompassed out-of-region and in-region combustion sources emitting mercury to the air that subsequently deposited to the surface, municipal wastewater treatment plants directly discharging to water, non-municipal wastewater discharges, and stormwater. Based on 1998 emissions, modeled atmospheric deposition contributed 97.9 percent of the total mercury load to the region’s waters, with the majority share coming from out-of-region sources. In order to achieve the target fish tissue mercury concentrations, the states determined it will require an at least 98 percent reduction in atmospheric mercury deposition arising from anthropogenic sources relative to 1998 levels.<sup>9</sup>

To address mercury released within their own borders, the Northeast states have been implementing multiple rules limiting mercury emissions from in-state emission sources. These measures have included limits on coal-fired power plants, medical waste incinerators, municipal waste combustors, and sewage sludge incinerators.<sup>10</sup> Initial measures reduced the modeled in-

<sup>8</sup> US EPA Region 1 letter to CT DEP, *Notification of Approval of Northeast Mercury TMDL* (December 20, 2007). New Jersey followed with its own successful mercury TMDL petition in 2009 [EPA Region 2 Decision Letter, *Review of Total Maximum Daily Load (TMDL) for Mercury Impairments Caused Mainly by Air Deposition in 122 HUC 14s Statewide, New Jersey (NJ)* (September 29, 2009)].

<sup>9</sup> New England Interstate Water Pollution Control Commission, *et al.*, *Northeast Regional Mercury Total Maximum Daily Load* (October 24, 2007). Available at <http://click.neiwpcc.org/mercury/mercury-docs/FINAL%20Northeast%20Regional%20Mercury%20TMDL.pdf> (accessed April 5, 2019).

<sup>10</sup> NESCAUM, *Tracking Progress in Reducing Mercury Air Emissions* (September 2007). Available at <http://www.nescaum.org/documents/northeast-states-succeed-in-reducing-mercury-in-the-environment/final->

region mercury deposition contribution attributable to Northeast state sources from 43 percent in 1998 to 19 percent in 2002. Conversely, the modeled relative in-region contribution from out-of-region sources (upwind states and international) rose from 57 percent in 1998 to 81 percent in 2002.<sup>11</sup>

While the Northeast states have made significant progress in reducing in-region mercury releases, these reductions will not be sufficient to ensure that fish are safe to eat unless comparable out-of-region national and international measures occur. According to the Northeast Regional Mercury TMDL analysis:

The Northeast region’s ability to achieve the calculated TMDL allocations is dependent on the adoption and effective implementation of national and international programs to achieve necessary reductions in mercury emissions. Given the magnitude of the reductions required to implement the TMDL, the Northeast cannot reduce in-region sources further to compensate for insufficient reductions from out-of-region sources. . . . Specifically, it is Northeast States’ position that the data and analyses in this TMDL demonstrate that: . . . (B.) EPA must implement significant reductions from upwind out-of-region sources, primarily coal-fired power plants; and (C.) MACT provisions of section 112(d) of the CAA should be adopted as the mechanism for implementing this TMDL.<sup>12</sup>

After having moved forward, however, EPA now seeks to reverse course by adopting a new and highly restrictive view of the value of the health and environmental benefits achieved by MATS. The new analysis dismisses the majority of the benefits associated with reducing EGU air toxics, and as a result, the Agency now asserts that the remaining benefits no longer justify the “appropriate and necessary” finding that forms the legal basis for MATS.

Although the Agency has not proposed withdrawing the MATS emission standards, if EPA were to finalize its withdrawal of the finding, it could pave the way for administrative appeal or expose MATS to future legal challenge that could result in a court striking down the standards, and put the Northeast states’ public health and environment at increased risk. Vacating MATS would create economic incentives for coal- and oil-fired EGUs not to operate, or operate at diminished effectiveness, their installed pollution controls where not required for other purposes.

---

<sup>11</sup> New England Interstate Water Pollution Control Commission, *et al.*, *Northeast Regional Mercury Total Maximum Daily Load* (October 24, 2007), at p. 7.

<sup>12</sup> *Ibid.* at p. 44.

As noted in this document, there is historical precedent for EGUs dialing back or turning off installed pollution controls when not required to operate them. Because the Northeast states are downwind from states with large coal- and oil-fired EGUs that lack their own state standards that could backup the loss of MATS, increased air toxic emissions from those states will result in increased deposition within the Northeast region.

This document provides a broader overview of the extent of the numerous impacts that HAPs emitted by coal- and oil-fired EGUs have on public health and the environment. Rather than fully accounting for these in its Reconsideration Proposal, EPA selectively ignores or overly discounts multiple other exposure pathways (e.g., most fish consumption pathways for mercury exposure) and multiple other benefits from reducing the public’s exposure through those pathways (e.g., decreased risk of fatal heart attacks and diabetes). EPA also discounts to zero the impacts of air toxics to the environment, such as known impacts of mercury on wildlife.

EPA also applies a new approach to cost-benefit analysis that is ill-suited for assessing the full benefits of reducing HAPs from coal- and oil-fired EGUs. EPA uses a cost-benefit approach that is overly narrow and heavily discounts or ignores hard to monetize benefits. This approach is incomplete and potentially misleading when applied to air toxics where many of the adverse impacts, hence benefits, occur over long time periods or are widely disbursed and difficult to directly link to a unique causal factor at a specific point in time. States that previously adopted their own multipollutant pollution control programs recognized that the full benefits of their rules were not always amenable to monetization,<sup>13</sup> and therefore considered the multiple health and environmental benefits using a broader set of considerations.

Furthermore, EPA, in a reversal of long-standing regulatory practice and at odds with the federal government’s own guidelines, dismisses the co-benefits from reductions in fine particulate matter that it asserts are not the “target pollutants” under MATS. Most non-mercury metal air toxics, however, are physically bound within primary particulate matter emitted by coal- and oil-fired EGUs and are reduced by using particulate matter pollution controls. Therefore, reductions in particulate matter are a natural and unavoidable consequence of the MATS requirements to reduce non-mercury metal air toxics. EPA’s revised approach ignores this direct relationship and

---

<sup>13</sup> See, e.g., Delaware Department of Natural Resources & Environmental Control, Division of Air & Waste Management, Air Quality Management Section, *Technical Support Document for Proposed Regulation No. 1146, Electric Generating Unit (EGU) Multi-Pollutant Regulation*, September 2006 (p. 62). Available at: [http://www.dnrec.delaware.gov/dwhs/Info/Regs/Documents/8969c5c8305d44318a38de77339cdf66multi\\_p\\_TechSp\\_tDoc1.pdf](http://www.dnrec.delaware.gov/dwhs/Info/Regs/Documents/8969c5c8305d44318a38de77339cdf66multi_p_TechSp_tDoc1.pdf).

assigns it no benefit.

Based on a fuller accounting of the health and environmental benefits as well as historical control costs of the MATS requirements, and consistent with long standing regulatory analysis prior to the narrow approach EPA adopts in the Reconsideration Proposal, we conclude that EPA lacks a reasonable basis for its proposed action and that it remains both appropriate and necessary to regulate toxic air emissions from coal- and oil-fired EGUs.

*b. NESCAUM background*

NESCAUM was established in 1967 as a forum among its northeastern state members to exchange technical information, promote cooperation in regard to air pollution control issues of regional concern, and assist the states in implementing national environmental programs required under the Clean Air Act and other federal legislation. To accomplish these objectives, NESCAUM facilitates technical committees and workgroups, sponsors frequent air quality trainings, participates in national discussions, and organizes a variety of research initiatives. Many of NESCAUM’s activities culminate in technical analyses, published reports, and workshops designed to provide support to our member states or disseminate state-of-the-art information concerning air pollution control issues.

With respect to air toxics, NESCAUM has been deeply involved over a number of years in the evaluation of their impacts on public health and the environment within the Northeast. These activities include:

- Analyzing the trace metal and sulfur content in wood fuels and heating oil sold in the Northeast;
- Reviewing control technologies to reduce conventional and hazardous air pollutants from coal-fired EGUs;
- Characterizing organic HAPs and other air pollutants from wood burning appliances;
- Evaluating relative cancer risks from conventional and reformulated gasolines;
- Quantifying the comparative contributions of different mercury pollution sources and source regions to mercury deposited from the air to land and water in the Northeast;
- Conducting state-level monitoring and modeling analyses of air toxics; and
- Improving source-specific estimates in mercury air emission inventories within the NESCAUM states.

A more complete listing of these and other NESCAUM activities with links to individual

documents is available at [www.nescaum.org](http://www.nescaum.org).

*c. Mercury and other hazardous air pollutants in the Northeast*

The EPA has presented a summary of the cancer and non-cancer impacts for mercury, the non-mercury toxic metals, acid gases, and organic HAPs, including dioxins/furans that the MATs rule addresses.<sup>14</sup> Mercury has received special attention as a health and environmental problem among the NESCAUM states. Mercury deposition from upwind sources has significantly affected aquatic and terrestrial environments in the Northeast, resulting in states having to issue fish consumption advisories to protect human health.

Over 15,000 fish samples collected in the Northeast confirm widespread mercury contamination of aquatic ecosystems, threatening human health and wildlife without broad regional efforts to reduce significant local and upwind sources of mercury emissions. Mercury contamination also threatens the tourist and recreational fishing industries, which contribute \$3 billion a year to the Northeast’s regional economy.

In a 1997 study, the EPA modeled the transport and deposition of mercury emissions associated with selected categories of major combustion and manufacturing sources, including coal- and oil-fired EGU boilers. The study showed that the Northeast had one of the highest annual mercury deposition rates in the country and that, in areas with flat terrain, at least 75 percent of the mercury emitted by the modeled facilities was transported more than 50 km downwind from the facility. Monitoring data corroborated the modeling results.<sup>15</sup>

In 2007, NESCAUM conducted a modeling study to apportion contributions, by geographical area and by source category, to mercury deposition in the NESCAUM region. The analysis used an emissions inventory<sup>16</sup> developed by NESCAUM for 2002, after controls were implemented in the region for three mercury emission source categories: municipal waste combustors; medical waste incinerators; and sewage sludge incinerators. The modeling study calculated that in 2002, upwind sources in states outside of the NESCAUM region were responsible for nearly 60% of the domestic U.S. contribution to deposition in the NESCAUM states; upwind EGUs alone were

responsible for 36% of those impacts.<sup>17</sup> As an outgrowth of this work, all the NESCAUM states, collectively or individually, petitioned EPA under the Clean Water Act to establish total maximum daily loads (TMDLs) for mercury entering the waters of the Northeast, which EPA approved.<sup>18</sup>

Working with the New England Interstate Water Pollution Control Commission (NEIWPCC), NESCAUM in 2008 used an EPA-sponsored modeling analysis<sup>19</sup> to further refine its previous results showing that much of the mercury entering the Northeast’s aquatic ecosystems is deposited from the air, and a significant portion of this mercury comes from emission sources outside the region. That analysis concluded that nearly half of the mercury associated with U.S. sources that is deposited across New York and the New England states comes from within these states and another 40 percent is attributable to sources in states immediately upwind, including Pennsylvania, New Jersey, Ohio, West Virginia, and Maryland.<sup>20</sup> As part of a Clean Water Act sec. 319(g) conference that focused on mercury TMDL water quality impairment issues in New York and the six New England states, EPA reviewed NESCAUM’s analysis and found its results virtually identical with EPA’s own results.<sup>21</sup>

While mercury receives a large share of the attention, other non-mercury air toxic emissions from coal- and oil-fired EGUs affect the Northeast. For example, researchers have implicated nickel emissions from oil combustion with an increased risk in daily mortality.<sup>22</sup> In the Northeast, EGUs burning No. 6 residual oil are a large source of these emissions.

*d. NESCAUM state efforts to reduce mercury released into the environment*

In light of the dangers posed by mercury contamination, the Northeast states have been aggressively regulating in-region mercury releases to the air for a number of years. These efforts have been aimed at reducing mercury in products entering into waste streams, in addition to direct releases into air and water. A summary of efforts in 2007 noted:

Since 2000, the Northeast states have enacted major legislation to address mercury use in products and ultimately in solid and hazardous waste. [...] Mercury collection and recycling efforts by the Northeast States led to an estimated 7.5 tons of mercury recovered from homes, schools, hospitals, and other locations throughout the region. Some of the actions that have contributed to these reductions include the recycling of 41,764 mercury-containing thermostats, the collection of 120,973 mercury automobile switches and 213,322 mercury thermometers, and the removal of 4,696 lb of mercury from 456 schools.<sup>23</sup>

Additional efforts among the Northeast states include adopting laws or regulations requiring the installation of dental amalgam separators in dental offices to reduce the amount of mercury going to wastewater treatment facilities. Strict emission limits on municipal waste combustors reduced their mercury air emissions in the Northeast states by 85% from the late 1990s, from more than 14,000 lb to approximately 2,000 lb of emitted mercury. Additional deep reductions have occurred from medical waste incinerators within the region, where state limits resulted in mercury decreases of greater than 95% from these sources, falling from almost 1,600 lb in 1998 to 58 lb in 2002.<sup>24</sup>

Prior to the federal MATS rule in 2011, the NESCAUM states had already begun imposing by rule or legislation stringent mercury limits on coal-fired EGUs, and these were largely in place by the mid-2000s. Emissions requirements for coal-fired EGUs adopted in the Northeast include the following:

- Connecticut enacted legislation in June 2003 requiring coal-fired units in the state to meet emissions requirements by July 1, 2008.<sup>25</sup>
- Massachusetts promulgated regulations in May 2004 to limit mercury emissions from

<sup>24</sup> *Ibid.*

<sup>25</sup> Connecticut General Statute section 22a-199 (2003).

four large coal-fired EGUs in the state relative to 2000-2001 levels.<sup>26</sup> The deadline for compliance with Phase 1 (minimum 85% mercury capture) of those requirements was January 1, 2008. Compliance with more stringent Phase II requirements (minimum of 95 percent mercury capture) was required by October 1, 2012.

- New Hampshire adopted state legislation calling for a state-wide 80 percent reduction in coal-fired EGU mercury emissions no later than July 1, 2013.<sup>27</sup>
- New Jersey adopted rules in August 2005 limiting mercury emissions from coal-fired boilers by December 15, 2007.<sup>28</sup>
- New York State adopted rules in 2007 capping mercury emissions from coal-fired EGUs in the years 2010-2014 and limiting those emissions by 2015.<sup>29</sup>

Many of these state emission limits are well below that required by the federal MATS rule.

*e. State rules did not impose significant burdens on costs of reliability*

Prior to EPA’s final promulgation of MATS, a number of states had already adopted stringent limitations on mercury emissions from new and existing fossil fuel EGUs, often as part of multi-pollutant programs that included control cost considerations for sulfur dioxide (SO<sub>2</sub>) and nitrogen oxides (NO<sub>x</sub>). Rules covering EGUs in Delaware,<sup>30</sup> Maryland,<sup>31</sup> Massachusetts,<sup>32</sup> New

Jersey,<sup>33</sup> New York,<sup>34</sup> and Wisconsin<sup>35</sup> are illustrative of the cost considerations taken by these states.

In their rulemakings, the states recognized a broader range of public health and environmental benefits and put these considerations within an overall cost context affecting the electric generation industry as well as consumers. For example, Delaware and New York estimated the impact of their rules on retail electricity prices. While they projected an increase in cost of electricity generation for the affected EGUs, they concluded that it was not of sufficient magnitude to expect increased rates for consumers.<sup>36,37</sup>

With state rules now having been in place for over a decade, the historical experience in the states that adopted mercury standards show that the control costs did not impose an unreasonable burden on the covered EGUs, did not cause a drastic rise in electricity rates, and did not undermine electric grid reliability. As discussed below, a retrospective analysis of the MATS implementation, which has comparable requirements to those in the state rules, showed that actual costs were lower than projected costs and did not adversely affect the reliability of the grid.<sup>38</sup>

## II. Control Costs

Actual control costs for EGUs to comply with MATS have been less than originally estimated by

<sup>38</sup> *White Stallion Energy Center, LLC v. EPA*, D.C. Circuit Case No. 12-1100, Motion of Industry Respondent Intervenors to Govern Future Proceedings, filed September 24, 2015 (*see* Declaration of James E. Staudt and accompanying exhibits).

EPA. A retrospective analysis of MATS compliance costs by industry representatives estimated those costs to be about \$2 billion annually, which is less than one-quarter of EPA’s prospective annual cost estimate of \$9.6 billion.<sup>39</sup> A number of factors contributed to the substantially lower actual compliance costs. These factors include:<sup>40</sup>

- 1) Improved dry sorbent injection and activated carbon injection technologies at significantly lower costs;
- 2) Significantly lower natural gas prices than EPA estimated; and
- 3) Less generation capacity installing fabric filters, dry flue gas desulfurization (FGD) systems, and wet FGD upgrades than EPA estimated.

It is not unusual for the actual costs of complying with air pollution regulations to be substantially lower than pre-compliance estimates. NESCAUM’s 2000 retrospective review of several air pollution programs found a repeated pattern of high EPA cost estimates and much higher industry cost projections (often by a factor of two or more) as rules were promulgated, with lower actual compliance costs once the programs were implemented. Examples of programs for which costs were prospectively overestimated include the California Low Emissions Vehicle program and requirements for SO<sub>2</sub> controls pursuant to Title IV of the Clean Air Act.<sup>41</sup>

### III. Northeast states will be adversely impacted if MATS requirements are rescinded

#### *a. Withdrawing the “appropriate and necessary” finding puts the MATS requirements at legal risk*

In EPA’s Reconsideration Proposal, the Agency does not propose to revoke the MATS standards (although it does invite comment on that option); EPA proposes only to withdraw the “appropriate and necessary” finding. Withdrawing the finding—which, under the Clean Air Act obligates EPA to regulate EGU HAPs—could render the MATS standards vulnerable to legal challenge. Should the MATS standards be vacated or rescinded by future legal or administrative action, it creates the threat that EGUs now in full compliance with MATS would stop operating their installed controls. This is not entirely speculation, as the following historical context shows.

---

<sup>39</sup> *Ibid.* Staudt Declaration.

<sup>40</sup> *Ibid.* Staudt Declaration.

<sup>41</sup> NESCAUM, *Environmental Regulation and Technology Innovation: Controlling Mercury Emissions from Coal-Fired Boilers*, September 2000. Available at: [http://www.nescaum.org/documents/rpt000906mercury\\_innovative-technology.pdf](http://www.nescaum.org/documents/rpt000906mercury_innovative-technology.pdf).

Ceasing operations of those controls would cause adverse impacts in downwind Northeast states.

*b. Operation of installed controls*

The initial MATS compliance deadline was April 16, 2015. According to the U.S. Energy Information Administration (EIA), coal-fired plants with a total capacity of 87 GW installed pollution-control equipment and nearly 20 GW of coal capacity was retired by that date. The EPA granted one-year extensions to coal plants with a total capacity of 142 GW, which allowed those facilities to operate until April 2016 while finalizing compliance strategies.<sup>42</sup>

An additional one-year extension, to April 2017, was granted to five plants with a combined capacity of 2.3 GW to ensure electric reliability. Two of those five plants were retired, one converted to natural gas, and one installed MATS-compliant controls by that date. The remaining plant, Oklahoma’s Grand River Energy Center, was given another emergency extension to July 2017 for reliability issues,<sup>43</sup> and complied with MATS requirements in 2017.<sup>44</sup>

There typically is a financial cost associated with operation of the controls used to remove regulated pollutants from EGU emissions.<sup>45</sup> As a result, there is an economic incentive for EGUs to discontinue operating pollution controls absent an enforceable obligation to do so under a permit, regulation, or court order.<sup>46</sup> For example, an analysis by the Ozone Transport Commission showed that in 2012, numerous coal-fired EGUs equipped with post-combustion NO<sub>x</sub> emission controls, in particular selective catalytic reduction controls, stopped or limited operation of those controls and instead chose to achieve compliance with the federal Clean Air Interstate Rule by purchasing NO<sub>x</sub> emissions allowances, presumably because it was less expensive to do so.<sup>47</sup> A specific example is the coal-fired Montour Power Plant in Pennsylvania,

---

<sup>45</sup> Examples of these costs are for the purchase of control reagents, parasitic energy load to run the controls, and additional operation and maintenance of the control equipment.

<sup>46</sup> McNevin, T.F., Recent increases in nitrogen oxide (NO<sub>x</sub>) emissions from coal-fired electric generating units equipped with selective catalytic reduction, 66 *JAWMA* 66-75 (2016), DOI: 10.1080/10962247.2015.1112317.

<sup>47</sup> See Statement from the Ozone Transport Commission Requesting the Use and Operation of Existing Control Devices Installed at Electric Generating Units (June 13, 2013), [http://www.otcair.org/upload/Documents/Formal%20Actions/Statement\\_EGUs.pdf](http://www.otcair.org/upload/Documents/Formal%20Actions/Statement_EGUs.pdf).

where a company spokesperson stated that in 2015, it was much cheaper to buy allowances than run its already installed NO<sub>x</sub> controls.<sup>48</sup>

Thus, there is precedent to expect that the coal-fired EGUs not located within the 11 states<sup>49</sup> requiring controls under state law will not operate or will limit operation of the controls that they installed to comply with MATS requirements if that rule is no longer in effect. This is particularly likely for controls specific to mercury reduction, such as activated carbon injection and halogen (e.g., bromine) addition, that cost money to operate and that can be readily turned off without affecting compliance with other non-mercury pollution control obligations.

Given that the majority of the nation’s coal-fired EGU capacity is located in states without state-based mercury controls—such as Indiana, Pennsylvania, Ohio, West Virginia, and Texas—uncontrolled mercury emissions in the event of full or partial vacatur or repeal of MATS could be substantial. Uncontrolled mercury emissions from Pennsylvania’s coal-fired EGUs are of particular concern to the NESCAUM states because Pennsylvania has numerous coal-fired EGUs and contributes significantly to mercury deposition in the NESCAUM states, due to its proximity to the region and prevailing weather patterns.<sup>50</sup>

*c. Impacts of mercury deposition on natural resources*

As documented in recent studies, reductions in mercury emissions associated with implementation of state and federal rules have resulted in decreased mercury levels in waterbodies and in freshwater and saltwater fish. Examples of studies documenting those reductions include:

- Core sediment samples taken from the Great Lakes and nearby lakes showed a 20% mean decline in mercury accumulation attributable to domestic emissions reductions.<sup>51</sup>
- Mercury concentrations in largemouth bass and yellow perch in lakes in a mercury

hotspot area of Massachusetts showed declines of 44% and 43%, respectively, between 1999 and 2011, a period in which major reductions in mercury air emissions from combustion sources occurred in the region.<sup>52</sup>

- A recent study convincingly linked mercury air emissions and mercury levels in saltwater fish tissue. The researchers reported that the concentration of mercury in bluefish collected off the North Carolina coast in 2011 was 43% lower than the concentration measured in 1972 and noted that this reduction, approximately 10% per decade, “is similar to estimated reductions of mercury observed in atmospheric deposition, riverine input, seawater, freshwater lakes, and freshwater fish across northern North America.” The authors also cited eight additional studies conducted between 1973 and 2007 that confirm the decrease in mercury levels in bluefish captured in the Mid-Atlantic Bight (defined as the continental shelf waters from Cape Cod, Massachusetts, to Cape Hatteras, North Carolina) with decreasing U.S. mercury air emissions.<sup>53</sup>

Decreases in mercury contamination of fish are associated with human health benefits, as discussed in the following subsection. In addition, a reduction in mercury contamination will decrease the detrimental impacts on fish and fish-eating wildlife, including:

- Impacts on insectivorous terrestrial species such as songbirds, bats, spiders, and amphibians;
- Reproductive effects, including deficits in sperm and egg formation, histopathological changes in testes and ovaries, and disruption of reproductive hormone synthesis in several fish species, including trout, bass (large and smallmouth), northern pike, carp, walleye and salmon;
- Significant adverse effects in breeding loons, including behavioral (reduced nest-sitting), physiological (flight feather asymmetry), and reproductive (chicks fledged/territorial pair) effects and reduced survival; and

- Effects on the white ibis and other piscivorous bird species, including decreased foraging efficiency, decreased reproductive success and altered pair behavior, resulting in a reduction in fledglings.<sup>54</sup>

Mercury contamination of fishing areas, largely due to atmospheric mercury deposition, has led many states, including the NESCAUM member states, to issue widespread fish consumption advisories. Advisories warn residents, particularly women of child bearing age, to avoid or severely curtail fish consumption. Wildlife are not able to choose to avoid these exposures. Without MATS to limit these mercury emissions, the Northeast states will have little chance to address these persistent harms to the region’s natural resources caused by EGUs located upwind and outside the region.

*d. Impacts of mercury deposition on human health*

As discussed above, emitted mercury, when deposited in or carried into waterbodies, is readily converted to methylmercury (MeHg), a particularly toxic and persistent form of mercury. MeHg bioconcentrates in the food chain, and, as a result, mercury levels in fish tissue can be as much as 10 to 100 million times greater than concentrations in water.<sup>55</sup> Therefore, consumption of fish, including freshwater fish and saltwater fish and shellfish, are the major route of human exposure to mercury.

Human health effects linked to mercury exposure include the following:

- Children exposed to MeHg during a mother’s pregnancy can experience persistent and lifelong IQ and motor function deficits. There is no known threshold below which these effects do not occur.<sup>56</sup>
- In adults, high levels of MeHg exposure have been associated with adverse cardiovascular effects, including increased risk of fatal heart attacks.<sup>57</sup>
- Other adverse health effects of MeHg exposure that have been identified in the scientific

literature include endocrine disruption,<sup>58</sup> diabetes risk,<sup>59</sup> and compromised immune function.<sup>60</sup>

EPA’s Regulatory Impact Analysis (RIA) in support of the MATS rule only monetized the effect of loss of IQ points for a certain subset of the exposed U.S. population. However, it is important that all of the health impacts listed above be carefully evaluated in any regulatory action that may increase mercury exposures. Consideration of cardiovascular effects is particularly critical. In 2011, a group of experts convened by EPA found “the body of evidence exploring the link between MeHg and acute myocardial infarction (MI) to be sufficiently strong to support its inclusion in future benefits analyses, based both on direct epidemiological evidence of an MeHg–MI link and on MeHg’s association with intermediary impacts that contribute to MI risk.”<sup>61</sup>

Note that fish with high MeHg levels also frequently have high levels of heart protective omega-3 fatty acids.<sup>62</sup> That correlation tends to mask the cardiovascular effects of MeHg in epidemiological studies and has made the development of quantitative risk factors for the MeHg-MI link more challenging. However, as discussed below, monetizing MI reductions associated with reduction in MeHg exposures would significantly increase the quantified benefits associated with the MATS rule.

As previously noted, a recent study convincingly linked decreased mercury air emissions with decreased concentrations of MeHg in bluefish captured in the Mid-Atlantic Bight (the continental shelf waters from Cape Cod, Massachusetts, to Cape Hatteras, North Carolina).<sup>63</sup> The study’s authors concluded that, assuming that bluefish are representative of other marine

predators, reduced mercury releases will result in lower mercury public mercury exposures associated with eating marine fish. Those reductions in mercury intakes will likely have the largest benefit for women living in Atlantic coastal areas, who have, on average, higher mean mercury blood levels than other U.S. women of child-bearing age, as documented in the National Health and Nutrition Examination Survey.<sup>64</sup>

Consistent with the bluefish findings, another study found declining mercury concentrations in bluefin tuna in the Northwest Atlantic Ocean, and the declines paralleled decreases in North American mercury emissions being exported to the North Atlantic.<sup>65</sup> Because tuna species collectively provide more mercury (~40%) to the U.S. population than any other source,<sup>66</sup> it is clear that there will be significant health and economic benefits associated with saltwater fish consumption that come from reducing U.S. EGU mercury emissions.

The absence of MATS would put at risk public health in the Northeast states from the consumption of mercury-tainted fish, while diminishing the important health benefits of a diet that includes fish. In addition, the vitality of the Northeast’s marine fisheries is put at risk, threatening the future prospects of an already stressed but economically important component of the Northeast states’ economies.

*e. Impacts on compliance with other Clean Air Act requirements*

The EPA has incorporated MATS into its 2011 emissions modeling platform that projects emission baselines into the future.<sup>67</sup> States rely upon these projections in developing pollution control strategies to attain and maintain national ambient air quality standards (NAAQS). For example, Connecticut has included EPA’s 2017 baseline projections for emissions of NO<sub>x</sub>, which include MATS reductions, in its most recent ozone state implementation plan (SIP) submittal.<sup>68</sup> While MATS may not specifically require limitations on NO<sub>x</sub> as an ozone precursor,

<sup>68</sup> Connecticut Department of Energy and Environmental Protection, *8-Hour Ozone Attainment Demonstration for*

EPA has included the program in its projections because of its impact on reducing ozone precursor emissions in Connecticut and upwind states. Similarly, EPA has previously credited sulfur dioxide and particulate matter reductions from MATS in concluding that these would help eastern states meet the revised daily and annual fine particulate matter NAAQS with no additional controls needed.<sup>69</sup> Removal of MATS alters those projections and undermines the states’ ability to achieve the relied-upon reductions associated with MATS to help attain and maintain compliance with the ozone and particulate matter national ambient air quality standards.

In addition to the national ambient air quality standards, EPA requires states to develop long-term strategies that address visibility-impairing haze in designated federally protected national parks and wilderness areas (“Class I areas”<sup>70</sup>), and these strategies must consider “Emission reductions due to ongoing air pollution control programs[.]”<sup>71</sup> As part of these considerations, EPA requires states with Class I areas to include MATS among the federal measures that they use to establish reasonable progress goals in their state haze plans.<sup>72</sup> In the NESCAUM region, four states have Class I areas – Maine, New Hampshire, New Jersey, and Vermont. Removal of MATS will hinder the ability of these and other states with Class I areas to achieve the reasonable progress goals in their haze plans.

#### IV. Co-benefits and non-monetized benefits of the MATS rule

In EPA’s Reconsideration Proposal, it adopts for the first time a cost-benefit approach in which benefits that can be monetized are virtually the only factors considered in its “appropriate and necessary” finding. This overly constrains EPA’s approach to one narrow slice of the full benefits reasonably attributable to MATS. EPA also for the first time dismisses the substantial

<sup>71</sup> 40 CFR 51.308(f)(2).

<sup>72</sup> 82 Fed. Reg. 3078-3129 (January 10, 2017), at 3092.

“co-benefits” from reductions in other air pollutants, most notably fine particulate matter, based on the assertion that these are not the intended target of MATS, therefore cannot be meaningfully considered. Neither of those drastic changes are consistent with good practice in economic analysis, and both contradict the federal government’s own guidance in conducting a regulatory impact analysis.

*a. Non-monetized benefits of HAP reductions*

EPA’s RIA for the MATS rule monetized only one exposure-health endpoint, loss of IQ points in children who were exposed prenatally to MeHg via maternal ingestion of self-caught freshwater fish. The RIA states that that endpoint was used because of “the availability of thoroughly-reviewed, high-quality epidemiological studies assessing IQ or related cognitive outcomes suitable for IQ estimation, and the availability of well-established methods and data for economic valuation of avoided IQ deficits.”<sup>73</sup>

EPA did not attempt to monetize the benefits of reducing risks of any of the other health and environmental endpoints associated with exposure to MeHg that are listed above, including the increased risk of myocardial infarction in adults. It also did not monetize the benefits associated with a reduction in MeHg in saltwater fish and in commercially purchased fish. The RIA states that EPA did not attempt to monetize those pathways for two reasons: “(1) for self-caught saltwater fish, we are unable to estimate the reduction in fish tissue methylmercury that would be associated with reductions in mercury deposition from U.S. EGUs, and (2) for commercially purchased ocean fish, it is nearly impossible to determine the source of the methylmercury in those fish, and thus we could not attribute mercury levels to U.S. EGUs.”<sup>74</sup> While NESCAUM recognizes that there are uncertainties in quantifying these exposures, it is essential that these pathways be included in any benefit analysis, because they are the main MeHg exposure pathways for most of the U.S. population.

*b. Expanded quantitative analyses of the benefits of HAP reductions*

Several recent analyses have estimated the benefits of the reductions in exposures to MeHg associated with lower EGU emissions. Those analyses, which have yielded benefit estimates that are considerably higher than those calculated in the RIA, include:

---

<sup>73</sup> US EPA, *Regulatory Impact Analysis for the Final Mercury and Air Toxics Standards*, EPA-452/R-11-011 (December 2011), Chapter 4.

<sup>74</sup> *Ibid.*

- A calculation of societal costs associated with exposure to MeHg in the U.S., including costs borne by the health care system, by the individual and the household, and by employers and insurers. Those costs were valued at \$4.8 billion per year.<sup>75</sup>
- Using a probabilistic model, researchers calculated that a 10% reduction in the U.S. population’s exposure to MeHg would be associated with a savings of \$860 million per year, based on reductions in fatal heart attacks and IQ gains.<sup>76</sup>
- A 2005 NESCAUM analysis calculated that the health benefits to the public associated with reduced EGU mercury emissions would be as high as \$4.9 billion (2000\$) per year. This analysis, which included health endpoints (e.g., cardiovascular effects and premature mortality) and exposure pathways (e.g., ocean-caught fish) that were not included in the RIA, assumed an EGU mercury emissions cap of 26 tons per year, based on an earlier EPA proposal. Because EPA’s final MATS rule resulted in a four-fold greater decrease in EGU mercury emissions below NESCAUM’s assumed 26 tons per year, the full health benefits of MATS would be even larger than suggested by NESCAUM’s 2005 estimates.<sup>77</sup>

*c. Consideration of benefits of HAP reductions that cannot be monetized*

It is essential that EPA also meaningfully account for benefits associated with the MATS rule that cannot be monetized, and do so for both human health and ecological benefits. Frequently, there is more information available to monetize costs than benefits. While the regulated community has incentive and resources to estimate compliance costs (and, as noted earlier, typically overestimates costs), it has no such incentive to monetize public benefits. While government can help fill this information imbalance, it often lacks the resources to do so. Furthermore, benefits that accrue over long time periods or are widely disbursed and difficult to directly link to a unique causal factor at a specific point in time may be overly discounted or completely ignored.

The Office of Management and Budget’s (OMB) guidance on best practices in conducting

<sup>76</sup> Rice, G.E., J.K. Hammitt, and J.S. Evans. A Probabilistic Characterization of the Health Benefits of reducing Methyl Mercury Intake in the United States, 44 *Environ. Sci. Technol.* 5216-5224 (2010), DOI:10.1021/es903359u.

<sup>77</sup> NESCAUM, *Economic Valuation of Human Health Benefits of Controlling Mercury Emissions from U.S. Coal-Fired Power Plants*, February 2005. Available at: <http://www.nescaum.org/documents/rpt050315mercuryhealth.pdf>.

regulatory analyses clearly supports serious consideration of all benefits, including those that cannot be monetized. The OMB’s 2003 Circular A-4 notes that “[w]hen important benefits and costs cannot be expressed in monetary units, benefit-cost analysis is less useful, and it can even be misleading, because the calculation of net benefits in such cases does not provide a full evaluation of all relevant benefits and costs.”<sup>78</sup>

States that have adopted their own rules limiting mercury emissions from EGUs also identified numerous important benefits associated with their rules that they were not able to fully monetize. Delaware, for example, stated that, “while it is evident that economic benefits will accrue,” it “was not able to obtain sources of information that quantify the economic impact of mercury emissions reductions on neurological effects, cardiovascular effects, genotoxic effects, immunotoxic effects, or ecological effects.”<sup>79</sup> Consistent with the OMB’s guidelines and states’ experiences, NESCAUM believes that the presently quantifiable benefits do not capture the full value of HAPs reductions associated with the MATS rule, making EPA’s proposed cost-benefit comparison incomplete and potentially misleading, thus necessitating the use of other approaches to better consider those benefits.

*d. Consideration of co-benefits from reduction of criteria pollutant exposures*

The EPA’s 2016 Supplemental Finding included a formal cost-benefit analysis that found the monetized benefits associated with implementation of the MATS rule far outweighed the costs of compliance. In the Supplemental Finding, EPA stated that while in its preferred approach it was not relying on the rule’s monetized co-benefits to reaffirm its “appropriate and necessary” finding, the results of its formal cost-benefit analysis provided further evidence in support of the basis for MATS.

In the current Reconsideration Proposal, EPA is proposing to reverse that finding because most of the monetized benefits calculated in the benefit-cost analysis are associated with what it views as ancillary reductions in non-HAP emissions. Specifically, most of the monetized benefits in the Supplemental Finding’s formal cost-benefit analysis are associated with reductions in fine particulate matter (PM<sub>2.5</sub>). Those reductions are a co-benefit of the installation of control

---

<sup>78</sup> Office of Management and Budget (OMB), *Circular A-4: Regulatory Analysis*, 2003, p. 10.

<sup>79</sup> Delaware Department of Natural Resources & Environmental Control, Division of Air & Waste Management, Air Quality Management Section, *Technical Support Document for Proposed Regulation No. 1146, Electric Generating Unit (EGU) Multi-Pollutant Regulation*, September 2006 (p. 62). Available at: [http://www.dnrec.delaware.gov/dwhs/Info/Regs/Documents/8969c5c8305d44318a38de77339cdf66multi\\_p\\_TechSp\\_tDoc1.pdf](http://www.dnrec.delaware.gov/dwhs/Info/Regs/Documents/8969c5c8305d44318a38de77339cdf66multi_p_TechSp_tDoc1.pdf).

technology that reduces emissions of PM<sub>2.5</sub>, nitrogen oxides and sulfur dioxide, as well as HAPs. Note that in addition to direct (primary) PM<sub>2.5</sub> emissions from EGUs, nitrogen oxides and sulfur dioxides emitted by EGUs react in the atmosphere to form secondary PM<sub>2.5</sub>.

The EPA’s minimization of the importance of co-benefits (also called ancillary benefits) in the Reconsideration Proposal contradicts guidance on this subject in OMB’s Circular A-4, which states the following:

Your analysis should look beyond the direct benefits and direct costs of your rulemaking and consider any important ancillary benefits and countervailing risks. An ancillary benefit is a favorable impact of the rule that is typically unrelated or secondary to the statutory purpose of the rulemaking (e.g., reduced refinery emissions due to more stringent fuel economy standards for light trucks) while a countervailing risk is an adverse economic, health, safety, or environmental consequence that occurs due to a rule and is not already accounted for in the direct cost of the rule (e.g., adverse safety impacts from more stringent fuel-economy standards for light trucks).

You should begin by considering and perhaps listing the possible ancillary benefits and countervailing risks. However, highly speculative or minor consequences may not be worth further formal analysis. Analytic priority should be given to those ancillary benefits and countervailing risks that are important enough to potentially change the rank ordering of the main alternatives in the analysis. In some cases, the mere consideration of these secondary effects may help in the generation of a superior regulatory alternative with strong ancillary benefits and fewer countervailing risks. For instance, a recent study suggested that weight-based, fuel-economy standards could achieve energy savings with fewer safety risks and employment losses than would occur under the current regulatory structure.<sup>80</sup>

OMB’s reiterated its position on this issue in draft guidance that it issued in 2017, which stated that “[t]he consideration of co-benefits, including the co-benefits associated with reduction of particulate matter, is consistent with standard accounting practices and has long been required under OMB Circular A-4.”<sup>81</sup>

---

<sup>80</sup> Office of Management and Budget (OMB), *Circular A-4: Regulatory Analysis*, 2003, p. 26.

<sup>81</sup> Office of Management and Budget (OMB), *2017 Draft Report to Congress on the Benefits and Costs of Federal Regulations and Agency Compliance with the Unfunded Mandates Reform Act*, 2017, p. 13.

In addition, EPA uses filterable particulate matter emitted by coal- and oil-fired EGUs as a surrogate for non-mercury metal air toxics because these metals are closely associated with filterable particulates.<sup>82</sup> Therefore, controls that reduce filterable particulate matter from coal- and oil-fired EGUs are responsible for achieving reductions of these non-mercury metals. As a factual matter, control of filterable particulates emitted from EGUs is integrally linked to control of most metal toxics emitted by the same facilities.

## V. Summary

Almost 20 years after EPA first found it “appropriate and necessary” to limit mercury and other air toxics emitted by coal- and oil-fired EGUs (and reaffirmed it twice), the Agency now proposes to withdraw the finding. In doing so, EPA presents no new scientific assessment that air toxics emitted by EGUs no longer threaten public health and the environment. Instead, EPA presents a drastically scaled-back approach to assessing the benefits from reducing EGU air toxic emissions. In doing so, EPA conducts a cost-benefit analysis where the Agency contrasts only one narrow slice of monetized benefits against an outdated and demonstrably wrong monetized set of control costs. As a practical matter and with no prior precedent, EPA is now dismissing all other benefits of MATS that it does not assign a dollar value to, which by implication is the same as assigning them a value of zero dollars.

Furthermore, EPA inexplicably ignores standard good accounting practice and federal OMB guidance by dismissing MATS co-benefits that it has itself recognized may be relied upon by states in developing strategies to achieve compliance with other Clean Air Act requirements.

By basing its proposal to withdraw its previous “appropriate and necessary” finding on a narrowly constrained cost-benefit analysis that is incapable of adequately considering all the impacts of the HAPs covered by MATS, EPA fails to provide an informed analysis. In reviewing a more complete and extensive record of the range of benefits achievable by the MATS rule, and recognizing the actual historical costs of MATS compliance, we conclude that EPA lacks a proper foundation for withdrawing its long-standing “appropriate and necessary” finding.
